DEVICE TEST

1, Explain behaviour of hub device

Hub is a layer 1 device, it helps to build a network when we use multiple devices more than 3 - example 1,2,3, 4,5 pcs when it receives data packets from 1 pc, it broadcasts to all devices who are connected to hub device it simply delivers data packet to all

2, Explain behaviour of switch device

Switch is the layer 2 device, it also helps to build a network when we use multiple devices more than 3 - example 1,2,3,4,5 pcs - it does the process of address learning - then broadcasts first and then unicasts the packets to the destination. Once it is aware of the MAC address of the destination, the switch maintains a MAC table noting the source MAC address of source or destination. We can use multiple switches to connect - for example 4 departments - each department can have 10 pcs, in this case a single broadcast domain appears

3, Explain behaviour of router device

Router is a layer 3 device, this resolves the problem created by switch - single broadcast domain. Router maintains a routing table - IP address and their corresponding interface. Router types are - modular and non-modular where in non-modular when required I can add the port - board to the router where I can increase the number of ports in the router. Router uses IP address for communication. To configure a router we need to connect PC thru console port available in router using DB95 cable, USB. Software used to configure router - PUTTY, HYPER TERMINAL. Router commands are configured in 3 levels-
1. User executive mode - UEM
2. Privilege mode - R
3. Global Config mode - router>, Router #, Router(config)#-

router> - user mode, router # - viewing, Router (config)# actual config -
